Abstract:

The hide reduction of Italian wine production showed the last evaluation by the ISTAT (national institute of statistical study) concerning wine product is differently splinted between red and white wine, and its geographical distribution is evidently changed.

Different grounds had to be considered, firstly the macroeconomic background but probably also the substitution effect between various types of the Italian wine productions.

In order to analyse the reasons and to evaluate every possible effects of different economic policy, in our work we will use Input-Output tables for 2000, 2001 and 2003 where wine production is disaggregated into white, red&rose and must. Such disaggregation is used both to evaluate changes in productive structures wine among three years studied and, with the Macro Multiplier approach, for estimate the optimal structures of policies related wine activities.
